SPECIFICATION

PRODUCTION OF HYDROXYLATED FATTY ACIDS
IN GENETICALLY MODIFIED PLANTS

CROSS-REFERENCE TO RELATED APPLICATION

10 This application is a continuation-in-part of U.S. patent
application Serial No. 08/320,982, filed October 11, 1994,
Sub A which itself is a continuation-in-part of U.S. patent
application Serial No. 08/314,596, filed September 26, 1994,
now abandoned. The entire contents of U.S. patent application
Serial No. 08/320,982 and U.S. patent application Serial No.
15 08/314,596 are hereby incorporated by reference and relied
upon.

GOVERNMENT RIGHTS

20 The invention described herein was made in the course of
work under grant number DE-FG02-94ER20133 from the U.S.
Department of Energy and grant No. MCB9305269 from the
National Science Foundation. Therefore, the U.S. Government
has certain rights under this invention.

25 TECHNICAL FIELD

The present invention concerns the identification of
nucleic acid sequences and constructs, and methods related
thereto, and the use of these sequences and constructs to
produce genetically modified plants for the purpose of
30 altering the fatty acid composition of plant oils, waxes and
related compounds.

DEFINITIONS

The subject of this invention is a class of enzymes that

introduce a hydroxyl group into several different fatty acids resulting in the production of several different kinds of hydroxylated fatty acids. In particular, these enzymes catalyze hydroxylation of oleic acid to 12-hydroxy oleic acid and icosenoic acid to 14-hydroxy icosenoic acid. Other fatty acids such as palmitoleic and erucic acids may also be substrates. Since it is not possible to refer to the enzyme by reference to a unique substrate or product, we refer to the enzyme throughout as kappa hydroxylase to indicate that the enzyme introduces the hydroxyl three carbons distal (i.e., away from the carboxyl carbon of the acyl chain) from a double bond located near the center of the acyl chain.

The following fatty acids are also the subject of this invention: ricinoleic acid, 12-hydroxyoctadec-*cis*-9-enoic acid (12OH-18:1^{cisΔ⁹}); lesquerolic acid, 14-hydroxy-*cis*-11-icosenoic acid (14OH-20:1^{cisΔ¹¹}); densipolic acid, 12-hydroxyoctadec-*cis*-9,15-dienoic acid (12OH-18:2^{cisΔ^{9,15}}); auricolic acid, 14-hydroxy-*cis*-11,17-icosadienoic acid (14OH-20:2^{cisΔ^{11,17}}); hydroxyerucic, 16-hydroxydocos-*cis*-13-enoic acid (16OH-22:1^{cisΔ¹³}); hydroxypalmitoleic, 12-hydroxyhexadec-*cis*-9-enoic (12OH-16:1^{cisΔ⁹}); icosenoic acid (20:1^{cisΔ¹¹}). It will be noted that icosenoic acid is spelled eicosenoic acid in some countries.

BACKGROUND

Extensive surveys of the fatty acid composition of seed oils from different species of higher plants have resulted in the identification of at least 33 structurally distinct

monohydroxylated plant fatty acids, and 12 different polyhydroxylated fatty acids that are accumulated by one or more plant species (reviewed by van de Loo et al. 1993). Ricinoleic acid, the principal constituent of the seed oil from the castor plant *Ricinus communis* (L.), is of commercial importance. We have previously described the cloning of a gene from this species that encodes a fatty acid hydroxylase, and the use of this gene to produce ricinoleic acid in transgenic plants of other species (see U.S. patent application Serial No. 08/320,982, filed October 11, 1994). The scientific evidence supporting the claims in that patent application were subsequently published (van de Loo et al., 1995). The use of the castor hydroxylase gene to also produce other hydroxylated fatty acids such as lesquerolic acid, densipolic acid, hydroxypalmitoleic, hydroxyerucic and auricolic acid in transgenic plants is the subject of this invention. In addition, the identification of a gene encoding a homologous hydroxylase from *Lesquerella fendleri*, and the use of this gene to produce these hydroxylated fatty acids in transgenic plants is the subject of this invention.

Castor is a minor oilseed crop. Approximately 50% of the seed weight is oil (triacylglycerol) in which 85-90% of total fatty acids are the hydroxylated fatty acid, ricinoleic acid. Oil pressed or extracted from castor seeds has many industrial uses based upon the properties endowed by the hydroxylated fatty acid. The most important uses are production of paints and varnishes, nylon-type synthetic polymers, resins, lubricants, and cosmetics (Atsmon 1989). In addition to oil,

the castor seed contains the extremely toxic protein ricin, allergenic proteins, and the alkaloid ricinine. These constituents preclude the use of the untreated seed meal (following oil extraction) as a livestock feed, normally an important economic aspect of oilseed utilization.

Furthermore, with the variable nature of castor plants and a lack of investment in breeding, castor has few favorable agronomic characteristics. For a combination of these reasons, castor is no longer grown in the United States and the development of an alternative domestic source of hydroxylated fatty acids would be attractive. The production of ricinoleic acid, the important constituent of castor oil, in an established oilseed crop through genetic engineering would be a particularly effective means of creating a domestic source.

Because there is no practical source of lesquerolic, densipolic and auricolic acids from plants that are adapted to modern agricultural practices, there is currently no large-scale use of these fatty acids by industry. However, the fatty acids would have uses similar to those of ricinoleic acid if they could be produced in large quantities at comparable cost to other plant-derived fatty acids (Smith 1985). Plant species, such as certain species in the genus *Lesquerella*, that accumulate a high proportion of these fatty acids, have not been domesticated and are not currently considered a practical source of fatty acids (Hirsinger, 1989). This invention represents a useful step toward the eventual production of these and other hydroxylated fatty

acids in transgenic plants of agricultural importance.

The taxonomic relationships between plants having similar or identical kinds of unusual fatty acids have been examined (van de Loo et al., 1993). In some cases, particular fatty acids occur mostly or solely in related taxa. In other cases there does not appear to be a direct link between taxonomic relationships and the occurrence of unusual fatty acids. In this respect, ricinoleic acid has now been identified in 12 genera from 10 families (reviewed in van de Loo et al., 1993). Thus, it appears that the ability to synthesize hydroxylated fatty acids has evolved several times independently during the radiation of the angiosperms. This suggested to us that the enzymes which introduce hydroxyl groups into fatty acids arose by minor modifications of a related enzyme. Indeed, as shown herein, the sequence similarity between $\Delta 12$ fatty acid desaturases and the kappa hydroxylase from castor is so high that it is not possible to unambiguously determine whether a particular enzyme is a desaturase or a hydroxylase on the basis of evidence in the scientific literature. Similarly, a patent application (PCT/US93/09987) that purports to teach the isolation and use of $\Delta 12$ fatty acid desaturases does not teach how to distinguish a hydroxylase from a desaturase. In view of the importance of being able to distinguish between these activities for the purpose of genetic engineering of plant oils, the utility of that application is limited to the several instances where direct experimental evidence (e.g., altered fatty acid composition in transgenic plants) was presented to support the assignment of function. A method for

distinguishing between fatty acid desaturases and fatty acid hydroxylases on the basis of amino acid sequence of the enzyme is also a subject of this invention.

5 A feature of hydroxylated or other unusual fatty acids is that they are generally confined to seed triacylglycerols, being largely excluded from the polar lipids by unknown mechanisms (Battey and Ohlrogge 1989; Prasad et al., 1987). This is particularly intriguing since diacylglycerol is a precursor of both triacylglycerol and polar lipid. With 10 castor microsomes, there is some evidence that the pool of ricinoleoyl-containing polar lipid is minimized by a preference of diacylglycerol acyltransferase for ricinoleate-containing diacylglycerols (Bafor et al. 1991). Analyses of vegetative tissues have generated few reports of unusual fatty 15 acids, other than those occurring in the cuticle. The cuticle contains various hydroxylated fatty acids which are interesterified to produce a high molecular weight polyester which serves a structural role. A small number of other exceptions exist in which unusual fatty acids are found in 20 tissues other than the seed.

The biosynthesis of ricinoleic acid from oleic acid in the developing endosperm of castor (*Ricinus communis*) has been studied by a variety of methods. Morris (1967) established in double-labeling studies that hydroxylation occurs directly by 25 hydroxyl substitution rather than via an unsaturated-, keto- or epoxy-intermediate. Hydroxylation using oleoyl-CoA as precursor can be demonstrated in crude preparations or microsomes, but activity in microsomes is unstable and

variable, and isolation of the microsomes involved a considerable, or sometimes complete loss of activity (Galliard and Stumpf, 1966; Moreau and Stumpf, 1981). Oleic acid can replace oleoyl-CoA as a precursor, but only in the presence of CoA, Mg^{2+} and ATP (Galliard and Stumpf, 1966) indicating that activation to the acyl-CoA is necessary. However, no radioactivity could be detected in ricinoleoyl-CoA (Moreau and Stumpf, 1981). These and more recent observations (Bafor et al., 1991) have been interpreted as evidence that the substrate for the castor oleate hydroxylase is oleic acid esterified to phosphatidylcholine or another phospholipid.

The hydroxylase is sensitive to cyanide and azide, and dialysis against metal chelators reduces activity, which could be restored by addition of $FeSO_4$, suggesting iron involvement in enzyme activity (Galliard and Stumpf, 1966). Ricinoleic acid synthesis requires molecular oxygen (Galliard and Stumpf, 1966; Moreau and Stumpf 1981) and requires NAD(P)H to reduce cytochrome b5 which is thought to be the intermediate electron donor for the hydroxylase reaction (Smith et al., 1992).

Carbon monoxide does not inhibit hydroxylation, indicating that a cytochrome P450 is not involved (Galliard and Stumpf, 1966; Moreau and Stumpf 1981). Data from a study of the substrate specificity of the hydroxylase show that all substrate parameters (i.e., chain length and double bond position with respect to both ends) are important; deviations in these parameters caused reduced activity relative to oleic acid (Howling et al., 1972). The position at which the hydroxyl was introduced, however, was determined by the

position of the double bond, always being three carbons distal. Thus, the castor acyl hydroxylase enzyme can produce a family of different hydroxylated fatty acids depending on the availability of substrates. Thus, as a matter of convenience, we refer to the enzyme throughout as a kappa hydroxylase (rather than an oleate hydroxylase) to indicate the broad substrate specificity.

The castor kappa hydroxylase has many superficial similarities to the microsomal fatty acyl desaturases (Browse and Somerville, 1991). In particular, plants have a microsomal oleate desaturase active at the $\Delta 12$ position. The substrate of this enzyme (Schmidt et al., 1993) and of the hydroxylase (Bafor et al., 1991) appears to be a fatty acid esterified to the *sn*-2 position of phosphatidylcholine. When oleate is the substrate, the modification occurs at the same position ($\Delta 12$) in the carbon chain, and requires the same cofactors, namely electrons from NADH via cytochrome b_5 and molecular oxygen. Neither enzyme is inhibited by carbon monoxide (Moreau and Stumpf, 1981), the characteristic inhibitor of cytochrome P450 enzymes.

There do not appear to have been any published biochemical studies of the properties of the hydroxylase enzyme(s) in *Lesquerella*.

Conceptual basis of the invention

In U.S. patent application No. 08/320,982, we described the use of a cDNA clone from castor for the production of ricinoleic acid in transgenic plants. As noted above,

biochemical studies by others had suggested that the castor hydroxylase may not have strict specificity for oleic acid but would also catalyze hydroxylation of other fatty acids such as icosenoic acid (20:1^{cisΔ11}) (Howling et al., 1972). Based on these studies, our previous application No. 08/320,982 noted in Example 2 that the expression of the castor hydroxylase in transgenic plants of species such as *Brassica napus* and *Arabidopsis thaliana* that accumulate fatty acids such as icosenoic acid (20:1^{cisΔ11}) and erucic acid (13-docosenoic acid; 22:1^{cisΔ13}) would be expected to accumulate some of the hydroxylated derivatives of these fatty acids due to the activity of the hydroxylase on these fatty acids. We have now obtained additional direct evidence for such a claim based on the production of ricinoleic, lesquerolic, densipolic and auricolic fatty acids in transgenic *Arabidopsis* plants and have included such evidence herein as Example 1.

In example three of the previous application, we taught the various methods by which the castor hydroxylase clone and sequences derived thereof could be used to identify other hydroxylase clones from plant species such as *Lesquerella fendleri* that are known to accumulate hydroxylated fatty acids in seed oils. In this continuation we have provided an example of the use of that aspect of the invention for the isolation of a novel hydroxylase gene from *Lesquerella fendleri*.

In view of the high degree of sequence similarity between Δ12 fatty acid desaturases and the castor hydroxylase (van de Loo et al., 1995), the validity of claims for the use of

desaturase or hydroxylase genes or sequences derived therefrom
for the identification of genes of identical function from
other species must be viewed with skepticism. In this
application, we teach a method by which hydroxylase genes can
be distinguished from desaturases and describe methods by
which $\Delta 12$ desaturases can be converted to hydroxylases by the
modification of the gene encoding the desaturases. A
mechanistic basis for the similar reaction mechanisms of
desaturases and hydroxylases was presented in the earlier
patent application (No. 08/320,982). Briefly, the available
evidence suggests that fatty acid desaturases have a similar
reaction mechanism to the bacterial enzyme methane
monooxygenase which catalyses a reaction involving oxygen-atom
transfer ($\text{CH}_4 \rightarrow \text{CH}_3\text{OH}$) (van de Loo et al., 1993). The cofactor
in the hydroxylase component of methane monooxygenase is
termed a μ -oxo bridged diiron cluster (FeOFe). The two iron
atoms of the FeOFe cluster are liganded by protein-derived
nitrogen or oxygen atoms, and are tightly redox-coupled by the
covalently-bridging oxygen atom. The FeOFe cluster accepts
two electrons, reducing it to the diferrous state, before
oxygen binding. Upon oxygen binding, it is likely that
heterolytic cleavage also occurs, leading to a high valent
oxoiron reactive species that is stabilized by resonance
rearrangements possible within the tightly coupled FeOFe
cluster. The stabilized high-valent oxoiron state of methane
monooxygenase is capable of proton extraction from methane,
followed by oxygen transfer, giving methanol. The FeOFe
cofactor has been shown to be directly relevant to plant fatty

acid modifications by the demonstration that castor stearyl-ACP desaturase contains this type of cofactor (Fox et al., 1993).

On the basis of the foregoing considerations, we hypothesized that the castor oleate hydroxylase is a structurally modified fatty acyl desaturase, based upon three arguments. The first argument involves the taxonomic distribution of plants containing ricinoleic acid. Ricinoleic acid has been found in 12 genera of 10 families of higher plants (reviewed in van de Loo et al., 1993). Thus, plants in which ricinoleic acid occurs are found throughout the plant kingdom, yet close relatives of these plants do not contain the unusual fatty acid. This pattern suggests that the ability to synthesize ricinoleic acid has arisen (and been lost) several times independently, and is therefore a quite recent divergence. In other words, the ability to synthesize ricinoleic acid has evolved rapidly, suggesting that a relatively minor genetic change in the structure of the ancestral enzyme was necessary to accomplish it.

The second argument is that many biochemical properties of castor kappa hydroxylase are similar to those of the microsomal desaturases, as discussed above (e.g., both preferentially act on fatty acids esterified to the sn-2 position of phosphatidylcholine, both use cytochrome b5 as an intermediate electron donor, both are inhibited by cyanide, both require molecular oxygen as a substrate, both are thought to be located in the endoplasmic reticulum).

The third argument stems from the discussion of oxygenase

cofactors above, in which it is suggested that the plant membrane bound fatty acid desaturases may have a μ -oxo bridged diiron cluster-type cofactor, and that such cofactors are capable of catalyzing both fatty acid desaturations and hydroxylations, depending upon the electronic and structural properties of the protein active site.

Taking these three arguments together, it was hypothesized that kappa hydroxylase of castor endosperm is homologous to the microsomal oleate Δ 12 desaturase found in all plants. The evidence supporting this hypothesis was disclosed in the previous patent application (No. 08/320,982). A number of genes encoding microsomal Δ 12 desaturases from various species have recently been cloned (Okuley et al., 1994) and substantial information about the structure of these enzymes is now known. Hence, in the following invention we teach how to use structural information about fatty acyl desaturases to isolate kappa hydroxylase genes of this invention. This example teaches the method by which any carbon-monoxide insensitive plant fatty acyl hydroxylase gene can be identified by one skilled in the art.

BRIEF DESCRIPTION OF THE DRAWINGS

Figures 1A-D show the mass spectra of hydroxy fatty acids standards (Figure 1A, O-TMS-methylricinoleate; Figure 1B, O-TMS-methyl densipoleate; Figure 1C, O-TMS-methyl-lesqueroleate; and Figure 1D, O-TMS-methylauricoleate).

Figure 2 shows the fragmentation pattern of

trimethylsilylated methyl esters of hydroxy fatty acids.

Figure 3A shows the gas chromatogram of fatty acids extracted from seeds of wild type *Arabidopsis* plants. Figure 3B shows the gas chromatogram of fatty acids extracted from seeds of transgenic *Arabidopsis* plants containing the *fah12* hydroxylase gene. The numbers indicate the following fatty acids: [1] 16:0; [2] 18:0; [3] 18:1^{cisΔ9}; [4] 18:2^{cisΔ9,12}; [5] 20:0; [6] 20:1^{cisΔ11}; [7] 18:3^{cisΔ9,12,15}; [8] 22:1^{cisΔ13}; [9] 24:1^{cisΔ13}; [10] ricinoleic acid; [11] densipolic acid; [12] lesquerolic acid; [13] auricolic acid.

SUMMARY OF THE INVENTION

This invention relates to plant fatty acyl hydroxylases. Methods to use conserved amino acid or nucleotide sequences to obtain plant fatty acyl hydroxylases are described. Also described is the use of cDNA clones encoding a plant hydroxylase to produce a family of hydroxylated fatty acids in

transgenic plants.

In a first embodiment, this invention is directed to recombinant DNA constructs which can provide for the transcription or transcription and translation (expression) of the plant kappa hydroxylase sequence. In particular, constructs which are capable of transcription or transcription and translation in plant host cells are preferred. Such constructs may contain a variety of regulatory regions including transcriptional initiation regions obtained from genes preferentially expressed in plant seed tissue. In a second aspect, this invention relates to the presence of such constructs in host cells, especially plant host cells which have an expressed plant kappa hydroxylase therein.

In yet another aspect, this invention relates to a method for producing a plant kappa hydroxylase in a host cell or progeny thereof via the expression of a construct in the cell. Cells containing a plant kappa hydroxylase as a result of the production of the plant kappa hydroxylase encoding sequence are also contemplated herein.

In another embodiment, this invention relates to methods of using a DNA sequence encoding a plant kappa hydroxylase for the modification of the proportion of hydroxylated fatty acids produced within a cell, especially plant cells. Plant cells having such a modified hydroxylated fatty acid composition are also contemplated herein.

In a further aspect of this invention, plant kappa hydroxylase proteins and sequences which are related thereto, including amino acid and nucleic acid sequences, are

contemplated. Plant kappa hydroxylase exemplified herein includes a *Lesquerella fendleri* fatty acid hydroxylase. This exemplified fatty acid hydroxylase may be used to obtain other plant fatty acid hydroxylases of this invention.

5 In a further aspect of this invention, a nucleic acid sequence which directs the seed specific expression of an associated polypeptide coding sequence is described. The use of this nucleic acid sequence or fragments derived thereof, to obtain seed-specific expression in higher plants of any coding sequence is contemplated herein.

DETAILED DESCRIPTION OF THE INVENTION

15 A genetically transformed plant of the present invention which accumulates hydroxylated fatty acids can be obtained by expressing the double-stranded DNA molecules described in this application.

20 A plant fatty acid hydroxylase of this invention includes any sequence of amino acids, such as a protein, polypeptide or peptide fragment, or nucleic acid sequences encoding such polypeptides, obtainable from a plant source which demonstrates the ability to catalyze the production of ricinoleic, lesquerolic, hydroxyerucic (16-hydroxydocos-cis-13-enoic acid) or hydroxypalmitoleic (12-hydroxyhexadec-cis-9-enoic) from CoA, ACP or lipid-linked monoenoic fatty acid
25 substrates under plant enzyme reactive conditions. By "enzyme reactive conditions" is meant that any necessary conditions are available in an environment (i.e., such factors as

temperature, pH, lack of inhibiting substances) which will permit the enzyme to function.

Preferential activity of a plant fatty acid hydroxylase toward a particular fatty acyl substrate is determined upon comparison of hydroxylated fatty acid product amounts obtained per different fatty acyl substrates. For example, by "oleate preferring" is meant that the hydroxylase activity of the enzyme preparation demonstrates a preference for oleate-containing substrates over other substrates. Although the precise substrate of the castor fatty acid hydroxylase is not known, it is thought to be a monounsaturated fatty acid moiety which is esterified to a phospholipid such as phosphatidylcholine. However, it is also possible that monounsaturated fatty acids esterified to phosphatidylethanolamine, phosphatidic acid or a neutral lipid such as diacylglycerol or a Coenzyme-A thioester may also be substrates. As noted above, significant activity has been observed in radioactive labelling studies using fatty acyl substrates other than oleate (Howling et al., 1972) indicating that the substrate specificity is for a family of related fatty acyl compounds. Because the castor hydroxylase introduces hydroxy groups three carbons from a double bond, proximal to the methyl carbon of the fatty acid we term the enzyme a kappa hydroxylase for convenience. Of particular interest, we envision that the castor kappa hydroxylase may be used for production of 12-hydroxy-9-octadecenoic acid (ricinoleate), 12-hydroxy-9-hexadecenoic acid, 14-hydroxy-11-eicosenoic acid, 16-hydroxy-13-docosanoic acid, 9-hydroxy-6-

octadecenoic acid by expression in plants species which produce the non-hydroxylated precursors. We also envision production of additionally modified fatty acids such as 12-hydroxy-9,15-octadecadienoic acid that result from desaturation of hydroxylated fatty acids (e.g., 12-hydroxy-9-octadecenoic acid in this example).

We also envision that future advances in the genetic engineering of plants will lead to production of substrate fatty acids, such as icosenoic acid esters, and palmitoleic acid esters in plants that do not normally accumulate such fatty acids. We envision that the invention described herein may be used in conjunction with such future improvements to produce hydroxylated fatty acids of this invention in any plant species that is amenable to directed genetic modification. Thus, the applicability of this invention is not limited in our conception only to those species that currently accumulate suitable substrates.

As noted above, a plant kappa hydroxylase of this invention will display activity towards various fatty acyl substrates. During biosynthesis of lipids in a plant cell, fatty acids are typically covalently bound to acyl carrier protein (ACP), coenzyme A (CoA) or various cellular lipids. Plant kappa hydroxylases which display preferential activity toward lipid-linked acyl substrate are especially preferred because they are likely to be closely associated with normal pathway of storage lipid synthesis in immature embryos. However, activity toward acyl-CoA substrates or other synthetic substrates, for example, is also contemplated

herein.

Other plant kappa hydroxylases are obtainable from the specific exemplified sequences provided herein. Furthermore, it will be apparent that one can obtain natural and synthetic plant kappa hydroxylases including modified amino acid sequences and starting materials for synthetic-protein modeling from the exemplified plant kappa hydroxylase and from plant kappa hydroxylases which are obtained through the use of such exemplified sequences. Modified amino acid sequences include sequences which have been mutated, truncated, increased and the like, whether such sequences were partially or wholly synthesized. Sequences which are actually purified from plant preparations or are identical or encode identical proteins thereto, regardless of the method used to obtain the protein or sequence, are equally considered naturally derived.

Thus, one skilled in the art will readily recognize that antibody preparations, nucleic acid probes (DNA and RNA) and the like may be prepared and used to screen and recover "homologous" or "related" kappa hydroxylases from a variety of plant sources. Typically, nucleic acid probes are labeled to allow detection, preferably with radioactivity although enzymes or other methods may also be used. For immunological screening methods, antibody preparations either monoclonal or polyclonal are utilized. Polyclonal antibodies, although less specific, typically are more useful in gene isolation. For detection, the antibody is labeled using radioactivity or any one of a variety of second antibody/enzyme conjugate systems that are commercially available.

Homologous sequences are found when there is an identity of sequence and may be determined upon comparison of sequence information, nucleic acid or amino acid, or through hybridization reactions between a known kappa hydroxylase and a candidate source. Conservative changes, such as Glu/Asp, Val/Ile, Ser/Thr, Arg/Lys and Gln/Asn may also be considered in determining sequence homology. Typically, a lengthy nucleic acid sequence may show as little as 50-60% sequence identity, and more preferably at least about 70% sequence identity, between the target sequence and the given plant kappa hydroxylase of interest excluding any deletions which may be present, and still be considered related. Amino acid sequences are considered homologous by as little as 25% sequence identity between the two complete mature proteins. (See generally, Doolittle, R.F., OF URFS and ORFS, University Science Books, CA, 1986.)

A genomic or other appropriate library prepared from the candidate plant source of interest may be probed with conserved sequences from the plant kappa hydroxylase to identify homologously related sequences. Use of an entire cDNA or other sequence may be employed if shorter probe sequences are not identified. Positive clones are then analyzed by restriction enzyme digestion and/or sequencing. When a genomic library is used, one or more sequences may be identified providing both the coding region, as well as the transcriptional regulatory elements of the kappa hydroxylase gene from such plant source. Probes can also be considerably shorter than the entire sequence. Oligonucleotides may be

used, for example, but should be at least about 10, preferably at least about 15, more preferably at least 20 nucleotides in length. When shorter length regions are used for comparison, a higher degree of sequence identity is required than for longer sequences. Shorter probes are often particularly useful for polymerase chain reactions (PCR), especially when highly conserved sequences can be identified (See Gould, et al., 1989 for examples of the use of PCR to isolate homologous genes from taxonomically diverse species).

When longer nucleic acid fragments are employed (>100 bp) as probes, especially when using complete or large cDNA sequences, one would screen with low stringencies (for example, 40-50°C below the melting temperature of the probe) in order to obtain signal from the target sample with 20-50% deviation, i.e., homologous sequences. (Beltz, et al. 1983).

In a preferred embodiment, a plant kappa hydroxylase of this invention will have at least 60% overall amino acid sequence similarity with the exemplified plant kappa hydroxylase. In particular, kappa hydroxylases which are obtainable from an amino acid or nucleic acid sequence of a castor or lesquerella kappa hydroxylase are especially preferred. The plant kappa hydroxylases may have preferential activity toward longer or shorter chain fatty acyl substrates. Plant fatty acyl hydroxylases having oleate-12-hydroxylase activity and eicosenoate-14-hydroxylase activity are both considered homologously related proteins because of in vitro evidence (Howling et al., 1972), and evidence disclosed herein, that the castor kappa hydroxylase will act on both

substrates. Hydroxylated fatty acids may be subject to further enzymatic modification by other enzymes which are normally present or are introduced by genetic engineering methods. For example, 14-hydroxy-11,17-eicosadienoic acid, which is present in some *Lesquerella* species (Smith 1985), is thought to be produced by desaturation of 14-hydroxy-11-eicosenoic acid.

Again, not only can gene clones and materials derived thereof be used to identify homologous plant fatty acyl hydroxylases, but the resulting sequences obtained therefrom may also provide a further method to obtain plant fatty acyl hydroxylases from other plant sources. In particular, PCR may be a useful technique to obtain related plant fatty acyl hydroxylases from sequence data provided herein. One skilled in the art will be able to design oligonucleotide probes based upon sequence comparisons or regions of typically highly conserved sequence. Of special interest are polymerase chain reaction primers based on the conserved regions of amino acid sequence between the castor kappa hydroxylase and the *L. fendleri* hydroxylase (SED ID NO:4). Details relating to the design and methods for a PCR reaction using these probes are described more fully in the examples.

It should also be noted that the fatty acyl hydroxylases of a variety of sources can be used to investigate fatty acid hydroxylation events in a wide variety of plant and in vivo applications. Because all plants synthesize fatty acids via a common metabolic pathway, the study and/or application of one plant fatty acid hydroxylase to a heterologous plant host may

be readily achieved in a variety of species.

Once the nucleic acid sequence is obtained, the transcription, or transcription and translation (expression), of the plant fatty acyl hydroxylases in a host cell is desired to produce a ready source of the enzyme and/or modify the composition of fatty acids found therein in the form of free fatty acids, esters (particularly esterified to glycerolipids or as components of wax esters), estolides, or ethers. Other useful applications may be found when the host cell is a plant host cell, *in vitro* and *in vivo*.

For example, by increasing the amount of an kappa hydroxylase available to the plant, an increased percentage of ricinoleate or lesqueroleate (14-hydroxy-11-eicosenoic acid) may be provided.

Kappa hydroxylase

By this invention, a mechanism for the biosynthesis of ricinoleic acid in plants is demonstrated. Namely, that a specific plant kappa hydroxylase having preferential activity toward fatty acyl substrates is involved in the accumulation of hydroxylated fatty acids in at least some plant species. The use of the terms ricinoleate or ricinoleic acid (or lesqueroleate or lesquerolic acid, densipoleate etc.) is intended to include the free acids, the ACP and CoA esters, the salts of these acids, the glycerolipid esters (particularly the triacylglycerol esters), the wax esters, the estolides and the ether derivatives of these acids.

The determination that plant fatty acyl hydroxylases are active in the *in vivo* production of hydroxylated fatty acids suggests several possibilities for plant enzyme sources. And in fact, hydroxylated fatty acids are found in some natural plant species in abundance. For example, three hydroxy fatty acids related to ricinoleate occur in major amounts in seed oils from various *Lesquerella* species. Of particular interest, lesquerolic acid is a 20 carbon homolog of ricinoleate with two additional carbons at the carboxyl end of the chain (Smith 1985). Other natural plant sources of hydroxylated fatty acids include but are not limited to seeds of the *Linum* genus, seeds of *Wrightia* species, *Lycopodium* species, *Strophanthus* species, *Convolvulaceae* species, *Calendula* species and many others (van de Loo et al., 1993).

Plants having significant presence of ricinoleate or lesqueroleate or desaturated other or modified derivatives of these fatty acids are preferred candidates to obtain naturally-derived kappa hydroxylases. For example, *Lesquerella densipila* contains a diunsaturated 18 carbon fatty acid with a hydroxyl group (van de Loo et al., 1993) that is thought to be produced by an enzyme that is closely related to the castor kappa hydroxylase, according to the theory on which this invention is based. In addition, a comparison between kappa hydroxylases and between plant fatty acyl hydroxylases which introduce hydroxyl groups at positions other than the 12-carbon of oleate or the 14-carbon of lesqueroleate or on substrates other than oleic acid and icosanoic acid may yield insights for protein modeling or other modifications to create

synthetic hydroxylases as discussed above. For example, on the basis of information gained from structural comparisons of the $\Delta 12$ desaturases and the kappa hydroxylase, we envision making genetic modifications in the structural genes for $\Delta 12$ desaturases that convert these desaturases to kappa-hydroxylases. We also envision making changes in $\Delta 15$ hydroxylases that convert these to hydroxylases with comparable substrate specificity to the desaturases (e.g., conversion of $18:2^{\Delta 9,12}$ to $15OH-18:2^{\Delta 9,12}$. Since the difference between a hydroxylase and a desaturases concerns the disposition of one proton, we envision that by systematically changing the charged groups in the region of the enzyme near the active site, we can effect this change.

Especially of interest are fatty acyl hydroxylases which demonstrate activity toward fatty acyl substrates other than oleate, or which introduce the hydroxyl group at a location other than the C12 carbon. As described above, other plant sources may also provide sources for these enzymes through the use of protein purification, nucleic acid probes, antibody preparations, protein modeling, or sequence comparisons, for example, and of special interest are the respective amino acid and nucleic acid sequences corresponding to such plant fatty acyl hydroxylases. Also as previously described, once a nucleic acid sequence is obtained for the given plant hydroxylase, further plant sequences may be compared and/or probed to obtain homologously related DNA sequences thereto and so on.

Genetic Engineering Applications

As is well known in the art, once a cDNA clone encoding a plant kappa hydroxylase is obtained, it may be used to obtain its corresponding genomic nucleic acid sequences thereto.

The nucleic acid sequences which encode plant kappa hydroxylases may be used in various constructs, for example, as probes to obtain further sequences from the same or other species. Alternatively, these sequences may be used in conjunction with appropriate regulatory sequences to increase levels of the respective hydroxylase of interest in a host cell for the production of hydroxylated fatty acids or study of the enzyme *in vitro* or *in vivo* or to decrease or increase levels of the respective hydroxylase of interest for some applications when the host cell is a plant entity, including plant cells, plant parts (including but not limited to seeds, cuttings or tissues) and plants.

A nucleic acid sequence encoding a plant kappa hydroxylase of this invention may include genomic, cDNA or mRNA sequence. By "encoding" is meant that the sequence corresponds to a particular amino acid sequence either in a sense or anti-sense orientation. By "recombinant" is meant that the sequence contains a genetically engineered modification through manipulation via mutagenesis, restriction enzymes, and the like. A cDNA sequence may or may not encode pre-processing sequences, such as transit or signal peptide sequences. Transit or signal peptide sequences facilitate the delivery of the protein to a given organelle and are

frequently cleaved from the polypeptide upon entry into the organelle, releasing the "mature" sequence. The use of the precursor DNA sequence is preferred in plant cell expression cassettes.

5 Furthermore, as discussed above the complete genomic sequence of the plant kappa hydroxylase may be obtained by the screening of a genomic library with a probe, such as a cDNA probe, and isolating those sequences which regulate expression in seed tissue. In this manner, the transcription and
10 translation initiation regions, introns, and/or transcript termination regions of the plant kappa hydroxylase may be obtained for use in a variety of DNA constructs, with or without the kappa hydroxylase structural gene. Thus, nucleic acid sequences corresponding to the plant kappa hydroxylase of
15 this invention may also provide signal sequences useful to direct transport into an organelle 5' upstream non-coding regulatory regions (promoters) having useful tissue and timing profiles, 3' downstream non-coding regulatory region useful as transcriptional and translational regulatory regions and may
20 lend insight into other features of the gene.

Once the desired plant kappa hydroxylase nucleic acid sequence is obtained, it may be manipulated in a variety of ways. Where the sequence involves non-coding flanking regions, the flanking regions may be subjected to resection,
25 mutagenesis, etc. Thus, transitions, transversions, deletions, and insertions may be performed on the naturally occurring sequence. In addition, all or part of the sequence may be synthesized. In the structural gene, one or more

codons may be modified to provide for a modified amino acid sequence, or one or more codon mutations may be introduced to provide for a convenient restriction site or other purpose involved with construction or expression. The structural gene may be further modified by employing synthetic adapters, linkers to introduce one or more convenient restriction sites, or the like.

The nucleic acid or amino acid sequences encoding a plant kappa hydroxylase of this invention may be combined with other non-native, or "heterologous", sequences in a variety of ways. By "heterologous" sequences is meant any sequence which is not naturally found joined to the plant kappa hydroxylase, including, for example, combination of nucleic acid sequences from the same plant which are not naturally found joined together.

The DNA sequence encoding a plant kappa hydroxylase of this invention may be employed in conjunction with all or part of the gene sequences normally associated with the kappa hydroxylase. In its component parts, a DNA sequence encoding kappa hydroxylase is combined in a DNA construct having, in the 5' to 3' direction of transcription, a transcription initiation control region capable of promoting transcription and translation in a host cell, the DNA sequence encoding plant kappa hydroxylase and a transcription and translation termination region.

Potential host cells include both prokaryotic and eukaryotic cells. A host cell may be unicellular or found in a multicellular differentiated or undifferentiated organism

depending upon the intended use. Cells of this invention may be distinguished by having a plant kappa hydroxylase foreign to the wild-type cell present therein, for example, by having a recombinant nucleic acid construct encoding a plant kappa hydroxylase therein.

Depending upon the host, the regulatory regions will vary, including regions from viral, plasmid or chromosomal genes, or the like. For expression in prokaryotic or eukaryotic microorganisms, particularly unicellular hosts, a wide variety of constitutive or regulatable promoters may be employed. Expression in a microorganism can provide a ready source of the plant enzyme. Among transcriptional initiation regions which have been described are regions from bacterial and yeast hosts, such as *E. coli*, *B. subtilis*, *Saccharomyces cerevisiae*, including genes such as beta-galactosidase, T7 polymerase, tryptophan E and the like.

For the most part, the constructs will involve regulatory regions functional in plants which provide for modified production of plant kappa hydroxylase with resulting modification of the fatty acid composition. The open reading frame, coding for the plant kappa hydroxylase or functional fragment thereof will be joined at its 5' end to a transcription initiation regulatory region such as the wild-type sequence naturally found 5' upstream to the kappa hydroxylase structural gene. Numerous other transcription initiation regions are available which provide for a wide variety of constitutive or regulatable, e.g., inducible, transcription of the structural gene functions. Among

transcriptional initiation regions used for plants are such regions associated with the structural genes such as for nopaline and mannopine synthases, or with napin, soybean β -conglycinin, oleosin, 12S storage protein, the cauliflower mosaic virus 35S promoters and the like. The transcription/translation initiation regions corresponding to such structural genes are found immediately 5' upstream to the respective start codons. In embodiments wherein the expression of the kappa hydroxylase protein is desired in a plant host, the use of all or part of the complete plant kappa hydroxylase gene is desired; namely all or part of the 5' upstream non-coding regions (promoter) together with the structural gene sequence and 3' downstream non-coding regions may be employed. If a different promoter is desired, such as a promoter native to the plant host of interest or a modified promoter, i.e., having transcription initiation regions derived from one gene source and translation initiation regions derived from a different gene source, including the sequence encoding the plant kappa hydroxylase of interest, or enhanced promoters, such as double 35S CaMV promoters, the sequences may be joined together using standard techniques.

For such applications when 5' upstream non-coding regions are obtained from other genes regulated during seed maturation, those preferentially expressed in plant embryo tissue, such as transcription initiation control regions from the *B. napus* napin gene, or the Arabidopsis 12S storage protein, or soybean β -conglycinin (Bray et al., 1987), or the *L. fendleri* kappa hydroxylase promoter described herein are

desired. Transcription initiation regions which are preferentially expressed in seed tissue, i.e., which are undetectable in other plant parts, are considered desirable for fatty acid modifications in order to minimize any disruptive or adverse effects of the gene product.

Regulatory transcript termination regions may be provided in DNA constructs of this invention as well. Transcript termination regions may be provided by the DNA sequence encoding the plant kappa hydroxylase or a convenient transcription termination region derived from a different gene source, for example, the transcript termination region which is naturally associated with the transcript initiation region. Where the transcript termination region is from a different gene source, it will contain at least about 0.5 kb, preferably about 1-3 kb of sequence 3' to the structural gene from which the termination region is derived.

Plant expression or transcription constructs having a plant kappa hydroxylase as the DNA sequence of interest for increased or decreased expression thereof may be employed with a wide variety of plant life, particularly, plant life involved in the production of vegetable oils for edible and industrial uses. Most especially preferred are temperate oilseed crops. Plants of interest include, but are not limited to rapeseed (Canola and high erucic acid varieties), Crambe, *Brassica juncea*, *Brassica nigra*, meadowfoam, flax, sunflower, safflower, cotton, *Cuphea*, soybean, peanut, coconut and oil palms and corn. An important criterion in the selection of suitable plants for the introduction on the kappa

hydroxylase is the presence in the host plant of a suitable substrate for the hydroxylase. Thus, for example, production of ricinoleic acid will be best accomplished in plants that normally have high levels of oleic acid in seed lipids.

5 Similarly, production of lesquerolic acid will best be accomplished in plants that have high levels of icosanoic acid in seed lipids.

10 Depending on the method for introducing the recombinant constructs into the host cell, other DNA sequences may be required. Importantly, this invention is applicable to dicotyledons and monocotyledons species alike and will be readily applicable to new and/or improved transformation and regulation techniques. The method of transformation is not critical to the current invention; various methods of plant transformation are currently available. As newer methods are available to transform crops, they may be directly applied hereunder. For example, many plant species naturally susceptible to *Agrobacterium* infection may be successfully transformed via tripartite or binary vector methods of
15 *Agrobacterium* mediated transformation. In addition, techniques of microinjection, DNA particle bombardment, electroporation have been developed which allow for the transformation of various monocot and dicot plant species.

20 In developing the DNA construct, the various components of the construct or fragments thereof will normally be inserted into a convenient cloning vector which is capable of replication in a bacterial host, e.g., *E. coli*. Numerous vectors exist that have been described in the literature.

After each cloning, the plasmid may be isolated and subjected to further manipulation, such as restriction, insertion of new fragments, ligation, deletion, insertion, resection, etc., so as to tailor the components of the desired sequence. Once the construct has been completed, it may then be transferred to an appropriate vector for further manipulation in accordance with the manner of transformation of the host cell.

Normally, included with the DNA construct will be a structural gene having the necessary regulatory regions for expression in a host and providing for selection of transformant cells. The gene may provide for resistance to a cytotoxic agent, e.g., antibiotic, heavy metal, toxin, etc., complementation providing prototrophy to an auxotrophic host, viral immunity or the like. Depending upon the number of different host species the expression construct or components thereof are introduced, one or more markers may be employed, where different conditions for selection are used for the different hosts.

It is noted that the degeneracy of the DNA code provides that some codon substitutions are permissible of DNA sequences without any corresponding modification of the amino acid sequence.

As mentioned above, the manner in which the DNA construct is introduced into the plant host is not critical to this invention. Any method which provides for efficient transformation may be employed. Various methods for plant cell transformation include the use of Ti- or Ri-plasmids, microinjection, electroporation, infiltration, imbibition, DNA

particle bombardment, liposome fusion, DNA bombardment or the like. In many instances, it will be desirable to have the construct bordered on one or both sides of the T-DNA, particularly having the left and right borders, more particularly the right border. This is particularly useful when the construct uses *A. tumefaciens* or *A. rhizogenes* as a mode for transformation, although the T-DNA borders may find use with other modes of transformation.

Where *Agrobacterium* is used for plant cell transformation, a vector may be used which may be introduced into the *Agrobacterium* host for homologous recombination with T-DNA or the Ti- or Ri-plasmid present in the *Agrobacterium* host. The Ti- or Ri-plasmid containing the T-DNA for recombination may be armed (capable of causing gall formation) or disarmed (incapable of causing gall), the latter being permissible, so long as the *vir* genes are present in the transformed *Agrobacterium* host. The armed plasmid can give a mixture of normal plant cells and gall.

In some instances where *Agrobacterium* is used as the vehicle for transforming plant cells, the expression construct bordered by the T-DNA border(s) will be inserted into a broad host spectrum vector, there being broad host spectrum vectors described in the literature. Commonly used is pRK2 or derivatives thereof. See, for example, Ditta et al., (1980), which is incorporated herein by reference. Included with the expression construct and the T-DNA will be one or more markers, which allow for selection of transformed *Agrobacterium* and transformed plant cells. A number of

markers have been developed for use with plant cells, such as resistance to kanamycin, the aminoglycoside G418, hygromycin, or the like. The particular marker employed is not essential to this invention, one or another marker being preferred depending on the particular host and the manner of construction.

For transformation of plant cells using *Agrobacterium*, explants may be combined and incubated with the transformed *Agrobacterium* for sufficient time for transformation, the bacteria killed, and the plant cells cultured in an appropriate selective medium. Once callus forms, shoot formation can be encouraged by employing the appropriate plant hormones in accordance with known methods and the shoots transferred to rooting medium for regeneration of plants. The plants may then be grown to seed and the seed used to establish repetitive generations and for isolation of vegetable oils.

The invention now being generally described, it will be more readily understood by reference to the following examples which are included for purposes of illustration only and are not intended to limit the present invention.

EXAMPLES

In the experimental disclosure which follows, all temperatures are given in degrees centigrade ($^{\circ}$), weights are given in grams (g), milligram (mg) or micrograms (μ g), concentrations are given as molar (M), millimolar (mM) or micromolar (μ M) and all volumes are given in liters (l),

microliters (μ l) or milliliters (ml), unless otherwise indicated.

5 EXAMPLE 1 - PRODUCTION OF NOVEL HYDROXYLATED FATTY ACIDS IN
 ARABIDOPSIS THALIANA

Overview

 The kappa hydroxylase encoded by the previously described
 fah12 gene from Castor (U.S. Patent application 08/320,982)
10 was used to produce ricinoleic acid, lesquerolic acid,
 densipolic acid and auricolic acid in transgenic Arabidopsis
 plants. This example reduces to practice the method taught in
 Example 2 of the foregoing application.

15 Production of transgenic plants

 A variety of methods have been developed to insert a DNA
 sequence of interest into the genome of a plant host to obtain
 the transcription and translation of the sequence to effect
 phenotypic changes. The following methods represent only one
20 of many equivalent means of producing transgenic plants and
 causing expression of the hydroxylase gene.

 Arabidopsis plants were transformed, by *Agrobacterium*-
 mediated transformation, with the kappa hydroxylase encoded by
 the Castor fah12 gene on binary Ti plasmid pB6. This plasmid
25 was previously used to transform *Nicotiana tabacum* for the
 production of ricinoleic acid (U.S. Patent application
 08/320,982).

 Inoculums of *Agrobacterium tumefaciens* strain GV3101

containing binary Ti plasmid pB6 were plated on L-broth plates containing 50 µg/ml kanamycin and incubated for 2 days at 30°C. Single colonies were used to inoculate large liquid cultures (L-broth medium with 50 mg/l rifampicin, 110 mg/l gentamycin and 200 mg/l kanamycin) to be used for the transformation of Arabidopsis plants.

Arabidopsis plants were transformed by the *in planta* transformation procedure essentially as described by Bechtold et al., (1993). Cells of *A. tumefaciens* GV3101(pB6) were harvested from liquid cultures by centrifugation, then resuspended in infiltration medium at OD₆₀₀ = 0.8 (Infiltration medium was Murashige and Skoog macro and micronutrient medium (Sigma Chemical Co., St. Louis, MO) containing 10 mg/l 6-benzylaminopurine and 5% glucose). Batches of 12-15 plants were grown for 3 to 4 weeks in natural light at a mean daily temperature of approximately 25°C in 3.5 inch pots containing soil. The intact plants were immersed in the bacterial suspension then transferred to a vacuum chamber and placed under 600 mm of vacuum produced by a laboratory vacuum pump until tissues appeared uniformly water-soaked (approximately 10 min). The plants were grown at 25°C under continuous light (100 µmol m⁻² s⁻¹ irradiation in the 400 to 700 nm range) for four weeks. The seeds obtained from all the plants in a pot were harvested as one batch. The seeds were sterilized by sequential treatment for 2 min with ethanol followed by 10 min in a mixture of household bleach (Chlorox), water and Tween-80 (50%, 50%, 0.05%) then rinsed thoroughly with sterile water. The seeds were plated at high density (2000 to 4000 per plate)

onto agar-solidified medium in 100 mm petri plates containing
1/2 X Murashige and Skoog salts medium enriched with B5
vitamins (Sigma Chemical Co., St. Louis, MO) and containing
kanamycin at 50 mg/l. After incubation for 48 h at 4°C to
stimulate germination, seedlings were grown for a period of
seven days until transformants were clearly identifiable as
healthy green seedlings against a background of chlorotic
kanamycin-sensitive seedlings. The transformants were
transferred to soil for two weeks before leaf tissue could be
used for DNA and lipid analysis. More than 20 transformants
were obtained.

DNA was extracted from young leaves from transformants to
verify the presence of an intact fah12 gene. The presence of
the transgene in a number of the putative transgenic lines was
verified by using the polymerase chain reaction to amplify the
insert from pB6. The primers used were HF2 =
GCTCTTTTGTGCGCTCATTC (SEQ ID NO:12) and HR1 =
CGGTACCAGAAAACGCCTTG (SEQ ID NO:13), which were designed to
allow the amplification of a 700 bp fragment. Approximately
100 ng of genomic DNA was added to a solution containing 25
pmol of each primer, 1.5 U Taq polymerase (Boehringer
Mannheim), 200 uM of dNTPs, 50 mM KCl, 10 mM Tris.Cl (pH 9),
0.1% (v/v) Triton X-100, 1.5 mM MgCl₂, 3% (v/v) formamide, to a
final volume of 50 µl. Amplifications conditions were: 4 min
denaturation step at 94°C, followed by 30 cycles of 92°C for 1
min, 55°C for 1 min, 72°C for 2 min. A final extension step
closed the program at 72°C for 5 min. Transformants could be
positively identified after visualization of a characteristic

1 kb amplified fragment on an ethidium bromide stained agarose gel. All transgenic lines tested gave a PCR product of a size consistent with the expected genotype, confirming that the lines were, indeed, transgenic. All further experiments were done with three representative transgenic lines of the wild type designated as 1-3, 4D, 7-4 and one transgenic line of the fad2 mutant line JB12. The transgenic JB12 line was included in order to test whether the increased accumulation of oleic acid in this mutant would have an effect on the amount of ricinoleic acid that accumulated in the transgenic plants.

Analysis of transgenic plants

Leaves and seeds from fah12 transgenic Arabidopsis plants were analyzed for the presence of hydroxylated fatty acids using gas chromatography. Lipids were extracted from 100-200 mg leaf tissue or 50 seeds. Fatty acid methyl esters (FAMES) were prepared by placing tissue in 1.5 ml of 1.0 M methanolic HCl (Supelco Co.) in a 13 x 100 mm glass screw-cap tube capped with a teflon-lined cap and heated to 80°C for 2 hours. Upon cooling, 1 ml petroleum ether was added and the FAMES removed by aspirating off the ether phase which was then dried under a nitrogen stream in a glass tube. One hundred μ l of N,O-bis(Trimethylsilyl) trifluoroacetamide (BSTFA; Pierce Chemical Co) and 200 μ l acetonitrile was added to derivatize the hydroxyl groups. The reaction was carried out at 70°C for 15 min. The products were dried under nitrogen, redissolved in 100 μ l chloroform and transferred to a gas chromatograph vial. Two μ l of each sample were analyzed on a SP2340 fused

silica capillary column (30 m, 0.75 mm ID, 0.20 mm film, Supelco), using a Hewlett-Packard 5890 II series Gas Chromatograph. The samples were not split, the temperature program was 195°C for 18 min, increased to 230°C at 25°C/min, held at 230°C for 5 min then down to 195°C at 25°C/min., and flame ionization detectors were used.

The chromatographic elution time of methyl esters and O-TMS derivatives of ricinoleic acid, lesquerolic acid and auricolic acid was established by GC-MS of lipid samples from seeds of *L. fendleri* and comparison to published chromatograms of fatty acids from this species (Carlson et al., 1990). A O-TMS-methyl-ricinoleate standard was prepared from ricinoleic acid obtained from Sigma Chemical Co (St, Louis, MO). O-TMS-methyl-lesqueroleate and O-TMS-methyl-auricoleate standards were prepared from triacylglycerols purified from seeds of *L. fendleri*. The mass spectrum of O-TMS-methyl-ricinoleate, O-TMS-methyl-densipoleate, O-TMS-methyl-lesqueroleate, and O-TMS-methyl-auricoleate are shown in Figures 1A-D, respectively. The structures of the characteristic ions produced during mass spectrometry of these derivatives are shown in Figure 2.

Lipid extracted from transgenic tissues were analyzed by gas chromatography and mass spectrometry for the presence of hydroxylated fatty acids. As a matter of reference, the average fatty acid composition of leaves in *Arabidopsis* wild type and *fad2* mutant lines was reported by Miquel and Browse (1992). Gas chromatograms of methylated and silylated fatty acids from seeds of wild type and a *fah12* transgenic wild type

plant are shown in Figures 3A and 3B, respectively. The profiles are very similar except for the presence of three small but distinct peaks at 14.3, 15.9 and 18.9 minutes. A very small peak at 20.15 min was also evident. The elution time of the peaks at 14.3 and 18.9 min corresponded precisely to that of comparably prepared ricinoleic and lesquerolic standards, respectively. No significant differences were observed in lipid extracts from leaves or roots of the wild type and the fah12 transgenic wild type lines (Table 1). Thus, in spite of the fact that the fah12 gene is expressed throughout the plant, we observed effects on fatty acid composition only in seed tissue. A similar observation was described previously for transgenic fah12 tobacco in patent application No. 08/320,982.

Table 1: Fatty acid composition of lipids from transgenic and wild type Arabidopsis. The values are the means obtained from analysis of samples from three independent transgenic lines, or three independent samples of wild type and fad2 lines.

Fatty acid	Seed				Leaf		Root	
	WT	FAH12/WT	FAH12/fad2	JB12	WT	FAH12/WT	WT	FAH12/WT
16:0	8.5	8.2	6.4	6.1	16.5	17.5	23.9	24.9
16:3	0	0	0	0	10.1	9.8	0	0
18:0	3.2	3.5	2.9	3.5	1.3	1.2	2.0	1.9
18:1	15.4	26.3	43.4	47.8	2.4	3.4	5.4	3.2
18:2	27.0	21.4	10.2	7.2	15.1	14.0	32.2	29.4
18:3	22.0	16.6	-	9.7	36.7	36.0	26.7	30.6
20:1	14.0	14.3	-	13.1	0	0	0	0
22:1	2.0	1.0	0.5	0.5	0	0	0	0
24:1	2.5	1.7	2.0	1.6	0	0	0	0
18:1-OH	0	0.4	0.3	0	0	0	0	0
18:2-OH	0	0.4	0.3	0	0	0	0	0
20:1-OH	0	0.2	0.1	0	0	0	0	0
20:2-OH	0	0.1	0.1	0	0	0	0	0

In order to confirm that the observed new peaks in the transgenic lines corresponded to derivatives of ricinoleic, lesquerolic, densipolic and auricollic acids, mass spectrometry was used. The fatty acid derivatives were resolved by gas chromatography as described above except that a Hewlett-Packard 5971 series mass selective detector was used in place of the flame ionization detector used in the previous experiment. The spectra of the four new peaks in Figure 3B (peak numbers 10, 11, 12 and 13) are shown in Figures 4A-D, respectively. Comparison of the spectrum obtained for the standards with that obtained for the four peaks from the transgenic lines confirms the identity of the four new peaks. On the basis of the three characteristic peaks at M/Z 187, 270 and 299, peak 10 is unambiguously identified as O-TMS-methylricinoleate. On the basis of the three characteristic peaks at M/Z 185, 270 and 299, peak 11 is unambiguously identified as O-TMS-methyldensipoleate. On the basis of the three characteristic peaks at M/Z 187, 298 and 327, peak 12 is unambiguously identified as O-TMS-methyllesqueroleate. On the basis of the three characteristic peaks at M/Z 185, 298 and 327, peak 13 is unambiguously identified as O-TS-methylauricoleate. These results unequivocally demonstrate the identity of the fah12 cDNA as encoding a hydroxylase that hydroxylates both oleic acid to produce ricinoleic acid and also hydroxylate icosenoic acid to produce lesquerolic acid. These results also provide additional evidence that the hydroxylase can be functionally expressed in a heterologous plant species in such a way that the enzyme is catalytically

functional. These results also demonstrate that expression of this hydroxylase gene leads to accumulation of ricinoleic, lesquerolic, densipolic and auricollic acids in a plant species that does not normally accumulate hydroxylated fatty acids in extractable lipids.

The presence of lesquerolic acid in the transgenic plants was anticipated in the previous patent application (No.

08/320,982) based on the biochemical evidence suggesting broad substrate specificity of the kappa hydroxylase. By contrast,

the accumulation of densipolic and auricollic acids was less predictable. Since Arabidopsis does not normally contain significant quantities of the non-hydroxylated precursors of these fatty acids which could serve as substrates for the hydroxylase, it appears that one or more of the three n-3

fatty acid desaturases known in Arabidopsis (eg., fad3, fad7, fad8; reviewed in Gibson et al., 1995) are capable of desaturating the hydroxylated compounds at the n-3 position.

That is, densipolic acid is produced by the action of an n-3 desaturase on ricinoleic acid. Auricollic acid is produced by

the action of an n-3 desaturase on lesquerolic acid. Because it is located in the endoplasmic reticulum, the fad3 desaturase is almost certainly responsible. This can be

tested in the future by producing fah12-containing transgenic plants of the fad3-deficient mutant of Arabidopsis (similar

experiments can be done with fad7 and fad8). It is also

formally possible that the enzymes that normally elongate

$18:1^{cis\Delta 9}$ to $20:1^{cis\Delta 11}$ may elongate $12OH-18:1^{cis\Delta 9}$ to $14OH-20:1^{cis\Delta 11}$,

and $12OH-18:2^{cis\Delta 9,15}$ to $14OH-20:2^{cis\Delta 11,17}$.

The amount of the various fatty acids in seed, leaf and root lipids of the control and transgenic plants is presented in Table 1. Although the amount of hydroxylated fatty acids produced in this example is less than desired for commercial production of ricinoleate and other hydroxylated fatty acids from plants, we envision numerous improvements of this invention that will increase the level of accumulation of hydroxylated fatty acids in plants that express the fah12 or related hydroxylase genes. Improvements in the level and tissue specificity of expression of the hydroxylase gene is envisioned. Methods to accomplish this by the use of strong, seed-specific promoters such as the *B. napus* napin promoter or the native promoters of the castor fah12 gene or the corresponding hydroxylase gene from *L. fendleri* will be obvious to one skilled in the art. Additional improvements are envisioned to involve modification of the enzymes which cleave hydroxylated fatty acids from phosphatidylcholine, reduction in the activities of enzymes which degrade hydroxylated fatty acids and replacement of acyltransferases which transfer hydroxylated fatty acids to the sn-1, sn-2 and sn-3 positions of glycerolipids. Although genes for these enzymes have not been described in the scientific literature, their utility in improving the level of production of hydroxylated fatty acids can be readily envisioned based on the results of biochemical investigations of ricinoleate synthesis.

Although *Arabidopsis* is not an economically important plant species, it is widely accepted by plant biologists as a

model for higher plants. Therefore, the inclusion of this example is intended to demonstrate the general utility of the invention described here and in the previous application (No. 08/320,982) to the modification of oil composition in higher plants. One advantage of studying the expression of this novel gene in Arabidopsis is the existence in this system of a large body of knowledge on lipid metabolism, as well as the availability of a collection of mutants which can be used to provide useful information on the biochemistry of fatty acid hydroxylation in plant species. Another advantage is the ease of transposing any of the information obtained on metabolism of ricinoleate in Arabidopsis to closely related species such as the crop plants *Brassica napus*, *Brassica juncea* or *Crambe Abyssinica* in order to mass produce ricinoleate, lesqueroleate or other hydroxylated fatty acids for industrial use. The kappa hydroxylase is useful for the production of ricinoleate or lesqueroleate in any plant species that accumulates significant levels of the precursors, oleic acid and icosanoic acid. Of particular interest are genetically modified varieties that accumulate high levels of oleic acid. Such varieties are currently available for sunflower and Canola. Production of lesquerolic acid and related hydroxy fatty acids can be achieved in species that accumulate high levels of icosanoic acid or other long chain monoenoic acids. Such plants may in the future be produced by genetic engineering of plants that do not normally make such precursors. Thus, we envision that the use of the kappa hydroxylase is of general utility.

EXAMPLE 2. ISOLATION OF LESQUERELLA KAPPA HYDROXYLASE GENOMIC CLONE

Overview

Regions of nucleotide sequence that were conserved in both the Castor kappa hydroxylase and the Arabidopsis fad2 $\Delta 12$ fatty acid desaturase were used to design oligonucleotide primers. These were used with genomic DNA from *Lesquerella fendleri* to amplify fragments of several homologous genes. These amplified fragments were then used as hybridization probes to identify full length genomic clones from a genomic library of *L. fendleri*. Hydroxylated fatty acids are specific to the seed tissue of *Lesquerella* sp., and are not found to any appreciable extent in vegetative tissues. One of the two genes identified by this method was expressed in both leaves and developing seeds and is therefore thought to correspond to the $\Delta 12$ fatty acid desaturase. The other gene was expressed at high levels in developing seeds but was not expressed or was expressed at very low levels in leaves and is the kappa hydroxylase from this species. The identity of this gene will be established by introducing the gene into transgenic Arabidopsis plants and showing that it causes the accumulation of ricinoleic acid, lesquerolic acid, densipolic acid and auricolic acid in seed lipids. The promoter of this gene is also of utility because it is able to direct expression of a gene specifically in developing seeds at a time when storage lipids are accumulating. This promoter is, therefore, of great utility for many applications in the genetic engineering

of seeds, particularly in members of the Brassicacea.

The various steps involved in this process are described in detail below. Unless otherwise indicated, routine methods for manipulating nucleic acids, bacteria and phage were as described by Sambrook et al. (1989).

Isolation of a fragment of the *Lesquerella kappa* hydroxylase gene

Oligonucleotide primers for the amplification of the *L. fendleri* kappa hydroxylase were designed by choosing regions of high deduced amino acid sequence homology between the Castor kappa hydroxylase and the Arabidopsis Δ12 desaturase (fad2). Because most amino acids are encoded several different codons, these oligonucleotides were designed to encode all possible codons that could encode the corresponding amino acids. The sequence of these mixed oligonucleotides was:

Oligo 1: TAYWSNCAYMGNMGNCAYCA (SEQ ID NO:14)

Oligo 2: RTGRTGNGCNACRTGNGTRTC (SEQ ID NO:15)

(Where: Y = C+T; W = A+T; S = G+C; N = A+G+C+T; M = A+C; R = A+G)

These oligonucleotides were used to amplify a fragment of DNA from *L. fendleri* genomic DNA by the polymerase chain reaction (PCR) using the following conditions: Approximately 100 ng of genomic DNA was added to a solution containing 25 pmol of each primer, 1.5 U Taq polymerase (Boehringer Mannheim), 200 uM of dNTPs, 50 mM KCl, 10 mM Tris.Cl (pH 9), 0.1% (v/v) Triton X-100, 1.5 mM MgCl₂, 3% (v/v) formamide, to a final volume of 50 μl. Amplifications conditions were: 4 min

denaturation step at 94°C, followed by 30 cycles of 92°C for 1 min, 55°C for 1 min, 72°C for 2 min. A final extension step closed the program at 72°C for 5 min.

5 PCR products of approximately 540 bp were observed following electrophoretic separation of the products of the PCR reaction in agarose gels. Two of these fragments were cloned into pBluescript (Stratagene) to give rise to plasmids pLesq2 and pLesq3. The sequence of the inserts in these two plasmids was determined by the chain termination method. The
10 sequence of the insert in pLesq2 is presented as Figure 5 (SEQ ID NO:1) and the sequence of the insert in pLesq3 is presented as Figure 6 (SEQ ID NO:2). The high degree of sequence identity between the two clones indicated that they were both
15 potential candidates to be either a $\Delta 12$ desaturase or a gamma hydroxylase.

Northern analysis

In *L. fendleri*, hydroxylated fatty acids are found in large amounts in seed oils but are not found in appreciable
20 amounts in leaves. Therefore, an important criterion in discriminating between a fatty acyl desaturase and kappa hydroxylase is that the kappa hydroxylase gene is expected to be expressed more highly in tissues which have high level of hydroxylated fatty acids than in other tissues whereas all
25 plant tissues should contain mRNA for an $\omega 6$ fatty acyl desaturase since diunsaturated fatty acids are found in the lipids of all tissues in most or all plants. Therefore, it was of great interest to determine whether the gene

corresponding to pLesq2 was also expressed only in seeds, or is also expressed in other tissues. This question was addressed by testing for hybridization of pLesq2 to RNA purified from developing seeds and from leaves.

5 Total RNA was purified from developing seeds and young leaves of *L. fendleri* using an Rneasy RNA extraction kit (Qiagen), according to the manufacturer's instructions. RNA concentrations were quantified by UV spectrophotometry at $\lambda=260$ and 280 nm. In order to ensure even loading of the gel to be used for Northern blotting, RNA concentrations were further adjusted after recording fluorescence under UV light of RNA samples stained with ethidium bromide and run on a test denaturing gel.

10 Total RNA prepared as described above from leaves and developing seeds was electrophoresed through an agarose gel containing formaldehyde (Iba et al., 1993). An equal quantity (10 μg) of RNA was loaded in both lanes, and RNA standards (0.16-1.77 kb ladder, Gibco-BRL) were loaded in a third lane. Following electrophoresis, RNA was transferred from the gel to a nylon membrane (Hybond N+, Amersham) and fixed to the filter by exposure to UV light. A ^{32}P -labelled probe was prepared from insert DNA of clone pLesq2 by random priming and hybridized to the membrane overnight at 52°C, after it had been prehybridized for 2 h. The prehybridization solution contained 5X SSC, 10X Denhardt's solution, 0.1% SDS, 0.1M KPO_4 , pH 6.8, 100 $\mu\text{g/ml}$ salmon sperm DNA. The hybridization solution had the same basic composition, but no SDS, and it contained 10% dextran sulfate and 30% formamide. The blot was

washed once in 2X SSC, 0.5% SDS at 65°C then in 1X SSC at the same temperature.

Brief (30 min) exposure of the blot to X-ray film revealed that the probe pLesq2 hybridized to a single band only in the seed RNA lane (Figure 7). The blot was re-probed with the insert from pLesq3 gene, which gave bands of similar intensity in the seed and leaf lanes (Figure 7).

These results show that the gene corresponding to the clone pLesq2 is highly and specifically expressed in seed of *L. fendleri*. In conjunction with knowledge of the nucleotide and deduced amino acid sequence, strong seed-specific expression of the gene corresponding to the insert in pLesq2 is a convincing indicator of the role of the enzyme in synthesis of hydroxylated fatty acids in the seed oil.

Characterization of a genomic clone of the gamma hydroxylase

Genomic DNA was prepared from young leaves of *L. fendleri* as described by Murray and Thompson (1980). A *Sau3AI*-partial digest genomic library constructed in the vector λ DashII (Stratagene, 11011 North Torrey Pines Road, La Jolla CA 92037) was prepared by partially digesting 500 μ g of DNA, size-selecting the DNA on a sucrose gradient (Sambrook et al., 1989), and ligating the DNA (12 kb average size) to the *Bam*HI-digested arms of λ DashII. The entire ligation was packaged according to the manufacturer's conditions and plated on *E. coli* strain XL1-Blue MRA-P2 (Stratagene). This yielded 5×10^5 primary recombinant clones. The library was then amplified according to the manufacturer's conditions. A fraction of the

genomic library was plated on *E. coli* XL1-Blue and resulting
plaques (150,000) were lifted to charged nylon membranes
(Hybond N+, Amersham), according to the manufacturer's
conditions. DNA was crosslinked to the filters under UV in a
Stratalinker (Stratagene).

Several clones carrying genomic sequences corresponding
to the *L. fenderi* hydroxylase were isolated by probing the
membranes with the insert from pLesq2 that was PCR-amplified
with internal primers and labelled with ³²P by random priming.
The filters were prehybridized for 2 hours at 65°C in 7% SDS,
1mM EDTA, 0.25 M Na₂HPO₄ (pH 7.2), 1% BSA and hybridized to
the probe for 16 hours in the same solution. The filters were
sequentially washed at 65°C in solutions containing 2 X SSC, 1
X SSC, 0.5 X SSC in addition to 0.1 % SDS. A 2.6 kb *Xba* I
fragment containing the complete coding sequence for the
gamma-hydroxylase and approximately 1 kb of the 5' upstream
region was subcloned into the corresponding site of
pBluescript KS to produce plasmid pLesq-Hyd and the sequence
determined completely using an automatic sequencer by the
dideoxy chain termination method. Sequence data was analyzed
using the program DNASIS (Hitachi company).

The sequence of the insert in clone pLesq-Hyd is shown in
Figures 8A-B. The sequence entails 1855 bp of contiguous DNA
sequence (SEQ ID NO:3). The clone encodes a 401 bp 5'
untranslated region (i.e., nucleotides preceding the first ATG
codon), an 1152 bp open reading frame, and a 302 bp 3'
untranslated region. The open reading frame encodes a 384
amino acid protein with a predicted molecular weight of 44,370

(SEQ ID NO:4). The amino terminus lacks features of a typical signal peptide (von Heijne, 1985).

The exact translation-initiation methionine has not been experimentally determined, but on the basis of deduced amino acid sequence homology to the Castor kappa hydroxylase (noted below) is thought to be the methionine encoded by the first ATG codon at nucleotide 402.

Comparison of the pLesq-Hyd deduced amino acid sequence with sequences of membrane-bound desaturases and the castor hydroxylase (Figures 9A-B) indicates that pLesq-Hyd is homologous to these genes. This figure shows an alignment of the *L. fendleri* hydroxylase (SEQ ID NO:4) with the castor hydroxylase (van de Loo et al. 1995), the Arabidopsis *fad2* cDNA which encodes an endoplasmic reticulum-localized $\Delta 12$ desaturase (called *fad2*) (Okuley et al., 1994), two soybean *fad2* desaturase clones, a *Brassica napus* *fad2* clone, a *Zea mays* *fad2* clone and partial sequence of a *R. communis* *fad2* clone. The high degree of sequence homology indicates that the gene products are of similar function. For instance, the overall homology between the Lesquerella hydroxylase and the Arabidopsis *fad2* desaturase was 92.2% similarity and 84.8% identity and the two sequences differed in length by only one amino acid.

Southern hybridization

Southern analysis was used to examine the copy number of the genes in the *L. fendleri* genome corresponding to the clone

pLesq-Hyd. Genomic DNA (5 μ g) was digested with *Eco*R I, *Hind* III and *Xba* I and separated on a 0.9% agarose gel. DNA was alkali-blotted to a charged nylon membrane (Hybond N+, Amersham), according to the manufacturer's protocol. The blot was prehybridized for 2 hours at 65°C in 7% SDS, 1mM EDTA, 0.25 M Na₂HPO₄ (pH 7.2), 1% BSA and hybridized to the probe for 16 hours in the same solution with pLesq-Hyd insert PCR-amplified with internal primers and labelled with ³²P by random priming. The filters were sequentially washed at 65°C in solutions containing 2 X SSC, 1 X SSC, 0.5 X SSC in addition to 0.1 % SDS, then exposed to X-ray film.

The probe hybridized with a single band in each digest of *L. fendleri* DNA (Figure 10), indicating that the gene from which pLesq-Hyd was transcribed is present in a single copy in the *L. fendleri* genome.

Expression of pLesq-Hyd in Transgenic Plants

There are a wide variety of plant promoter sequences which may be used to cause tissue-specific expression of cloned genes in transgenic plants. For instance, the napin promoter and the acyl carrier protein promoters have previously been used in the modification of seed oil composition by expression of an antisense form of a desaturase (Knutson et al. 1992). Similarly, the promoter for the β -subunit of soybean β -conglycinin has been shown to be highly active and to result in tissue-specific expression in transgenic plants of species other than soybean (Bray et al., 1987). Thus, although we describe the use of the *L. fendleri*

kappa hydroxylase promoter in the examples described here, other promoters which lead to seed-specific expression may also be employed for the production of modified seed oil composition. Such modifications of the invention described here will be obvious to one skilled in the art.

Constructs for expression of *L. fendleri* kappa hydroxylase in plant cells are prepared as follows: A 13 kb *Sall* fragment containing the pLesq-Hyg gene was ligated into the *XhoI* site of binary Ti plasmid vector pSLJ44026 (Jones et al., 1992) (Figure 11) to produce plasmid pTi-Hyd and transformed into *Agrobacterium tumefaciens* strains GV3101 by electroporation. Strain GV3101 (Koncz and Schell, 1986) contains a disarmed Ti plasmid. Cells for electroporation were prepared as follows. GV3101 was grown in LB medium with reduced NaCl (5 g/l). A 250 ml culture was grown to $OD_{600} = 0.6$, then centrifuged at 4000 rpm (Sorvall GS-A rotor) for 15 min. The supernatant was aspirated immediately from the loose pellet, which was gently resuspended in 500 ml ice-cold water. The cells were centrifuged as before, resuspended in 30 ml ice-cold water, transferred to a 30 ml tube and centrifuged at 5000 rpm (Sorvall SS-34 rotor) for 5 min. This was repeated three times, resuspending the cells consecutively in 30 ml ice-cold water, 30 ml ice-cold 10% glycerol, and finally in 0.75 ml ice-cold 10% glycerol. These cells were aliquoted, frozen in liquid nitrogen, and stored at -80C. Electroporations employed a Biorad Gene pulsar instrument using cold 2 mm-gap cuvettes containing 40 μ l cells and 1 μ l of DNA in water, at a voltage of 2.5 KV, and 200 Ohms

resistance. The electroporated cells were diluted with 1 ml SOC medium (Sambrook et al., 1989, page A2) and incubated at 28°C for 2-4 h before plating on medium containing kanamycin (50 mg/l).

5 *Arabidopsis thaliana* can be transformed with the *Agrobacterium* cells containing pTi-Hyd as described in Example 1 above. Similarly, the presence of hydroxylated fatty acids in the transgenic *Arabidopsis* plants can be demonstrated by the methods described in Example 1 above.

10 Constitutive expression of the *L. fendleri* hydroxylase in transgenic plants

15 A 1.5 kb *EcoR* I fragment from pLesq-Hyg comprising the entire coding region of the hydroxylase was gel purified, then cloned into the corresponding site of pBluescript KS (Stratagene). Plasmid DNA from a number of recombinant clones was then restricted with *Pst* I, which should cut only once in the insert and once in the vector polylinker sequence. Release of a 920 bp fragment with *Pst* I indicated the right orientation of the insert for further manipulations. DNA from one such clone was further restricted with *Sal*I, the 5' overhangs filled-in with the Klenow fragment of DNA polymerase I, then cut with *Sac* I. The insert fragment was gel purified, and cloned between the *Sma* I and *Sac* I sites of pBI121 (Clontech) behind the Cauliflower Mosaic Virus 35S promoter. After checking that the sequence of the junction between insert and vector DNA was appropriate, plasmid DNA from a

recombinant clone was used to transform *A. tumefaciens* (GV3101). Kanamycin resistant colonies were then used for *in planta* transformation of *A. thaliana* as previously described.

DNA was extracted from kanamycin resistant seedlings and used to PCR-amplify selected fragments from the hydroxylase using nested primers. When fragments of the expected size could be amplified, corresponding plants were grown in the greenhouse or on agar plates, and fatty acids extracted from fully expanded leaves, roots and dry seeds. GC-MS analysis was then performed as previously described to characterize the different fatty acid species and detect accumulation of hydroxy fatty acids in transgenic tissues.

EXAMPLE 3 - OBTAINING OTHER PLANT FATTY ACYL HYDROXYLASES

In a previous patent application, we described the ways in which the castor *fah12* sequence could be used to identify other kappa hydroxylases by methods such as PCR and heterologous hybridization. However, because of the high degree of sequence similarity between $\Delta 12$ desaturases and kappa hydroxylases, prior art does not teach how to distinguish between the two kinds of enzymes without a functional test such as demonstrating activity in transgenic plants or another suitable host (e.g., transgenic microbial or animal cells). The identification of the *L. fendleri* hydroxylase provided for the development of criteria by which a hydroxylase and a desaturase may be distinguished solely on the basis of deduced amino acid sequence information.

Figures 9A-B show a sequence alignment of the castor and

L. fendleri hydroxylase sequences with the castor hydroxylase sequence and all publically available sequences for all plant microsomal $\Delta 12$ fatty acid desaturases. Of the 384 amino acid residues in the castor hydroxylase sequence, more than 95% are identical to the corresponding residue in at least one of the desaturase sequences. Therefore, none of these residues are responsible for the catalytic differences between the hydroxylase and the desaturases. Of the remaining 16 residues in the castor hydroxylase and 14 residues in the *Lesquerella* hydroxylase, all but six represent instances where the hydroxylase sequence has a conservative substitution compared with one or more of the desaturase sequences, or there is wide variability in the amino acid at that position in the various desaturases. By conservative, we mean that the following amino acids are functionally equivalent : Ser/Thr, Ile/ Leu/ Val/ Met, Asp/ Glu. Thus, these structural differences also cannot account for the catalytic differences between the desaturases and hydroxylases. This leaves just six amino acid residues where both the castor hydroxylase and the *Lesquerella* hydroxylase differ from all of the known desaturases and where all of the known microsomal $\Delta 12$ desaturases have the identical amino acid residue. These residues occur at positions 69, 111, 155, 226, 304 and 331 of the alignment in Figure 9. Therefore, these six sites distinguish hydroxylases from desaturases. Based on this analysis, we claim that any enzyme with greater than 60% sequence identity to one of the enzymes listed in Figure 9 can be classified as a hydroxylase if it differs from the sequence of the desaturases at these six

positions. Because of slight differences in the number of residues in a particular protein, the numbering may vary from protein to protein but the intent of the number system will be evident if the protein in question is aligned with the castor hydroxylase using the numbering system shown herein. Thus, in conjunction with the methods for using the lesquerella hydroxylase gene to isolate homologous genes, the structural criterion disclosed here teaches how to isolate and identify plant kappa hydroxylase genes for the purpose of genetically modifying fatty acid composition as disclosed herein and in the previous application (No. 08/320,982).

In considering which of the six substitutions are solely or primarily responsible for the difference in catalytic activity of the hydroxylases of this invention and the desaturases, we consider it likely that the substitution of a Phe for a Tyr at position 226 may be solely responsible for this difference in catalytic activity because of the known participation of tyrosine radicals in enzyme catalysis. Other substitutions, such as the Ala for Ser at position 331 may have effects at modulating the overall rate of the reaction. On this basis we envision creating novel kappa hydroxylases by site directed mutagenesis of $\Delta 12$ desaturases. We also envision converting $\Delta 15$ desaturases and $\Delta 9$ desaturases to hydroxylases by similar use of site-directed mutagenesis.

CONCLUDING REMARKS

By the above examples, demonstration of critical factors in the production of novel hydroxylated fatty acids by

expression of a kappa hydroxylase gene from Castor in transgenic plants is described. In addition, a complete cDNA sequence of the *Lesquerella fendleri* kappa hydroxylase is also provided. A full sequence of the castor hydroxylase is also given with various constructs for use in host cells. Through this invention, one can obtain the amino acid and nucleic acid sequences which encode plant fatty acyl hydroxylases from a variety of sources and for a variety of applications.

All publications mentioned in this specification are indicative of the level of skill of those skilled in the art to which this invention pertains. All publications are herein incorporated by reference to the same extent as if each individual publication was specifically and individually indicated to be incorporated by reference.

Although the foregoing invention has been described in some detail by way of illustration and example for purposes of clarity of understanding, it will be obvious that certain changes and modifications may be practiced within the scope of the appended claims.
